Digital security is an important issue in a world where access to information over the Internet is a common activity. As the Internet expands, the number of systems that contain some type of digital information increases. These systems may be used for many different tasks. The use of documents containing digital information is a common task. Some documents may contain only text, while others may contain a combination of text and graphics, pictures, videos, and the like. Even text documents may sometimes include images and other types of digital information. A system may contain a copy of the text for each document within the system. Digital information and the systems in which digital information is stored are vulnerable to computer viruses. These viruses are often designed to damage or destroy information. As a result of this vulnerability, digital information may be subject to damage by computer viruses which may be malicious or destructive, or may be inadvertent. A computer virus is a program which is deliberately designed to disrupt or attack the system and which replicates itself so that it can gain control over the system. A virus may adversely affect a system, causing it to crash or lock up. It may corrupt critical system resources so that the system will not operate properly, or may even render the system totally useless. Viruses are often embedded in other programs, such as e-mail attachments and operating system files. There are many viruses and other threats to digital information, each with its own specific characteristics and behaviors. Some viruses are designed to attack only particular machines, while others may attack a very large number of machines indiscriminately. A virus may be intentionally destructive in nature, such as deleting important files. However, many viruses are simply designed to proliferate themselves 6d1f23a050
