The server will read only the keys it needs, and return an error code telling whether the key can be used.1. Field of the Invention This invention relates to memory circuits and, more particularly, to a method and system for increasing performance of an integrated circuit including a memory, such as a synchronous DRAM (SDRAM) memory. 2. Description of the Relevant Art Today, the most widely used synchronous DRAM (SDRAM) memory is the double data rate (DDR) SDRAM. DDR SDRAMs are capable of transferring data at twice the clock rate of conventional SDRAMs. Because of the advantages of higher data bandwidth (i.e., data transfer rate), DDR SDRAMs are widely employed in the computer and networking industries. The high data bandwidth performance, however, does present certain problems. For example, in some applications (e.g., computer networking and telephony), it is important to ensure that data packets are accurately stored and retrieved from memory. The most important of these is that packets to be stored within the memory must be properly aligned with the memory address. Thus, the packet must begin at the right address. Packets may be aligned either in the header or body portion. It is common practice to use internal read commands and external (RAS) commands to initiate packet transfers. In

general, the internal read command is carried within the packet (header) to ensure packet alignment. The RAS command is used to request the start of a packet. Once the RAS command is activated, the controller will wait for a suitable number of cycles to allow the packet to be aligned within the memory. The time necessary to ensure that an internal command has been applied and received (internal latency) is a function of the command latency and the number of cycles needed to align the packet. The number of cycles needed to align a packet depends on the specific operating mode of the memory.
